1 Abstract

2 Introduction

The valence electrons on lanthanide cations were thought to not participate in bonding due to the limited radial extent of the f -orbitals. Ln^{2+} complexes with $4f^n 5d^1$ configurations were recently synthesized, which could lead to the formation of metal-metal bonds. The aim of this experiment is to investigate the possibility of Y-Y bonding in the recently synthesized bimetallic complex $[(\text{Cp})_2\text{Y}(\mu\text{-H})]_2$.

Recent studies in Ln^{2+} complexes revealed that ligand field splitting can lower the energy of d -orbitals and lead to the formation of bimetallic lanthanide and actinide complexes.

3 Methods

3.1 Statement of the Models

In a lanthanide, the $4f$ orbitals are much closer to the nuclei compared to the $5d$ orbital. Electrons removed from the system will come from the $5d$ atomic orbital first, increasing the energy of the orbital while not affecting the $4f$ atomic orbital as much. As the oxidation state increases, the energy separation between the two orbitals decreases.

Orbital localization is expected to have no effect on the total energy of a molecule, nor the molecular structure. The orbital energies are expected to increase when localization is applied.

3.2 Computational Details

A DFT calculation was performed on B_2H_6 using the TPSSh functional and def2-SVP basis sets. The diborane molecule was assigned D_{2h} symmetry. Boys

localization was performed after lowering to C_1 symmetry. The canonical Kohn-Sham molecular orbitals and Boys localized orbitals were plotted.

Ground state optimizations of $[(\text{Cp})_2\text{Y}(\mu\text{-H})]_2$ and its monoanion were performed at the TPSSh level using def2-SVP basis sets. Solvation of the complexes in THF was simulated with a dielectric constant of 7.58. The HOMO-LUMO gaps of different spin states were analyzed to determine which one the molecule would be in. The spin states of the complexes was used to determine whether the complex would be EPR active. Frontier orbitals were visualized to determine whether metal-metal bonding was observed.

4 Results and Discussion

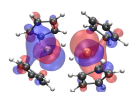

Orbital	Assignment	Table 1: Canonical		Assignment	Localized	
		Energy (eV)	Visualization		Energy (eV)	Visualization
HOMO (1b2g)	$\pi_{\text{p-p}}^*$	-8.514		$\sigma_{\text{s-p}}^*$	-10.726	
HOMO-1 (3ag)	$\sigma_{\text{p-p}}$	-9.867		$\sigma_{\text{s-p}}^*$	-10.726	
HOMO-2 (1b3u)	$\pi_{\text{p-p}}$	-10.156		$\sigma_{\text{s-p}}^*$	-10.726	
HOMO-3 (1b2u)	$\pi_{\text{p-p}}$	-11.516		$\sigma_{\text{s-p}}^*$	-10.726	
HOMO-4 (2b1u)	$\sigma_{\text{s-s}}^*$	-12.067		$\sigma_{\text{s-p}}^*$	-13.927	
HOMO-5 (2ag)	$\sigma_{\text{s-s}}$	-17.747		$\sigma_{\text{s-p}}^*$	-13.927	

The HOMO-LUMO gap of the neutral singlet complex is +4.29684 eV, whereas the neutral triplet complex yields a negative gap. A doublet state is the only reasonable spin state for the monoanion complex without exciting the electron. The doublet state has a smaller HOMO-LUMO gap than the neutral closed-shell complex of +0.74691 eV, and the excited quartet state also has a negative gap. The closed shell spin state of the neutral complex makes it EPR inactive, whereas the lone electron on the monoanion makes it EPR active. The bond length between the metal centers in the complex are 354.55pm and 346.19pm for the neutral and monoanion complex, respectively. This corresponds to a 0.724% error and a 0.344% error respectively when compared to Dumas et al. [1] The frontier orbitals of the monoanion complex are visualized in Figure 1.

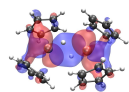

5 Conclusions
